Our goal is to sustainably reduce feed resources required to produce beef via the rapid development and deployment of novel nutritional, genomic and genetic improvement technologies.

We will strengthen the international competitiveness of US agriculture and enable increased food production by increasing the animal protein produced without additional feed inputs and with a reduced greenhouse gas footprint.

What is the project?

- ✓ The project involves a consortium of scientists, industry partners, breed associations, and cattle producers who will collect DNA samples and feed intake, growth and carcass composition data from over 8,000 animals (8 breeds).
- ✓ Over 2,400 animals will be genotyped for 770,000 SNPs each to generate across-breed molecular expected progeny differences (**MEPDs**) for feed efficiency, feed intake, growth and carcass traits.
- ✓ In addition to creating and validating selection tools for producers, we will also be examining the DNA of efficient animals and seeking straightforward methods to identify efficient animals without measurement of individual intakes.
- ✓ Part of this is developing tools for marker assisted selection (MAS) but also includes tools for marker assisted management (MAM). MAM is application of specific management practices (e.g. diet, days on feed, etc.) based on an animal's genotype so it reaches a given outcome group (i.e. choice) with the least feed inputs.

Why is this important?

A 1% improvement in feed efficiency has the same economic impact as a 3% increase in rate of gain.

The traits that beef producers routinely record are outputs which determine the value of product sold and not the inputs defining the cost of beef production. The inability to routinely measure feed intake and feed efficiency on large numbers of cattle has precluded the efficient application of selection despite moderate heritabilities ($h^2 = 0.08-0.46$). Feed accounts for approximately 65% of total beef production costs and 60% of the total cost of calf and yearling finishing systems. The cow-calf segment consumes about 70% of the calories; 30% are used by growing and finishing systems.

Table 1 demonstrates the potential cost savings to the US beef cattle industry that could occur with selection for feed intake, feed efficiency, growth, and carcass traits. Calves and yearlings selected for residual feed intake (RFI) have the same ADG but eat less feed thus saving feedlot operators money. Assuming 27 million cattle are fed per year and 34% of cattle in the feedlot are calves and 66% are yearlings, the beef industry could save over a billion dollars by reducing average daily feed intake by just 2 pounds.

This project is supported by Agriculture and Food Research Initiative Competitive Grant no. 2011-68004-30214 from the USDA National Institute of Food and Agriculture.

Table 1. Estimated cost savings to the US beef cattle industry from selection for a 2 pound reduction in residual feed intake.

| In Wt. | Out Wt. | Lb. Gain | ADG | Days on Feed | RFI | Reduced Feed Intake (lb) | Feed Cost Savings \$/hd | % of Fed Mix | Total Feed Cost Savings |
|--|---------|----------|-----|--------------|------|--------------------------|-------------------------|--------------|-------------------------|
| Calf Feds | | | | | | | | | |
| 600 | 1250 | 650 | 3.5 | 186 | 0.0 | 0 | | | |
| 600 | 1250 | 650 | 3.5 | 186 | -2.0 | -372 | (54.72) | 34 | \$ 502,620,656 |
| Yearling Feds | | | | | | | | | |
| 775 | 1300 | 525 | 4.0 | 131 | 0.0 | 0 | | | |
| 775 | 1300 | 525 | 4.0 | 131 | -2.0 | -262 | (38.67) | 66 | \$ 689,539,820 |
| Total Savings: \$ 1,192,160,476 | | | | | | | | | |

Annual fed slaughter cattle: 27 million head; Delivered feed cost: \$ 294.62 as fed
Weaber, 2011

How will this benefit me?

You will have genetic selection tools and techniques (**MEPDs**) that will allow you to create a cow herd that is more efficient at converting nutrients to calf gain. Additionally, the steers and heifers you send to a feedlot will use less feed to produce the same amount of high quality protein for human consumption.

Will this really work?

- ✓ MEPDs have been successfully employed for output traits (i.e. growth and carcass) on a within-breed basis in beef cattle. Results from the dairy industry have shown tremendous advantages, particularly in evaluating young sires, through the use of MEPDs.
- ✓ A large demonstration project that aims to illustrate the efficacy of tools developed from this project includes a group of approximately 20 seedstock producers from seven states representing the seven major U.S. beef breeds along with a large commercial ranch. Producer owned sires will be used to generate crossbred progeny that will have growth, feed intake and carcass data collected. These steer progeny and their sires will be genotyped.
- ✓ The demonstration component enables a validation of discovery work from the project and a visible demonstration utilizing academic and industry resources working towards a common goal, the development and employment of genomic tools to improve feed efficiency.
- ✓ Producer collaborators will provide DNA samples on females within their herds to examine the relationship between female fertility/longevity and feed efficiency. Inclusion of fertility/longevity traits in the project enables selection decisions to be made with a more complete understanding of potential genetic antagonisms across a suite of economically important beef production traits.

How can I participate?

Send your email address to: beefcenter@iastate.edu and indicate your interest in receiving updates about the website currently in development, meetings, presentations, and/or software availability. We will make certain you are put on the mailing list for updates.
